Future of Work @ Presight

Human API Business Review

Review date · 27 October 2026

Concept and local MVP review: current progress, evidence, value assumptions, decisions, and a proposed path to a safe pilot.

Agenda

Human API: concept and local MVP review

01	Executive view and decision	Decision
02	Product and roadmap status	Progress
03	Evaluation and safety	Evidence
04	Business case	Assumptions
05	Required decisions	Leadership
06	Outlook and risks	Pilot gate

Prove safety and value before a pilot

Project status

Local MVP

The local demo runs the question flow using fictional employees and files. It checks owner policy and requester access, cites evidence, routes gaps to a person, and requires approval before reusing corrections.

The single most important insight

The scripted checks pass, but there is no measured employee value, live Microsoft tenant, or real-user pilot.

Bottom line

The base estimate is AED 700k in time value versus AED 740k in annual cost. The AED 40k gap is illustrative; time value is not cash savings.

Leadership decision required

Sponsor a security and privacy review, then confirm each person can access only files their work account permits. Choose one willing team and use non-sensitive files.

What is proven so far—and what is not

Current position

The local app demonstrates the workflow on fictional data. Microsoft connections and employee value remain unproven.

Working workflow

Question records, owner rules, file checks, cited answers, escalation, and correction approval run locally.

Synthetic checks

17 backend tests and 36 of 36 written search cases passed. No real employees or tenant were tested.

Illustrative value

50,000 possible annual questions and AED 700k base time value are planning assumptions, not measured results.

Microsoft readiness

Microsoft sign-in and file access are not connected or tested in a work account. There is no Teams app or language model.

Business outcomes have not yet been measured

Current evidence is prototype-level

The local app demonstrates a question being saved, checked against owner and requester permissions, answered with a source, or routed to a person.

17 backend tests and all 36 written retrieval cases passed. These small fictional fixtures do not prove production accuracy, security, or value.

Local workflow

Question handling and approval run with synthetic people and files.

Scripted checks

17 backend tests and 36 search examples passed.

No live outcomes

No employee pilot, tenant proof, or time-savings study yet.

Three controls keep the workflow governed

Before any file is used

Owner consent limits dates, projects, topics, audience, and selected sources.

The requester must already be allowed to open a file. Access is checked before search and again before a saved answer is shown.

Owner opt-in

The owner chooses the scope and can pause or revoke the policy.

Requester access

Owner consent never gives another person new file access.

Human fallback

Missing or conflicting evidence goes to an approved person; reuse waits for owner approval.

Strategic focus: connect before building more

Test a narrow handoff workflow on top of search tools already in use.

Existing tools already search files, cite sources, and respect permissions.

Possible gap: owner-approved deadlines, source limits, human handoff, and approved reuse.

First test this workflow inside Teams or Copilot Studio.

Can Microsoft tools configure this same lifecycle at lower cost?

Compare a configured workflow with the Human API prototype before funding a standalone service.

Public vendor claims change; recheck availability and licensing before a decision.

The idea looks useful; its unique value is unproven

Human API should manage a controlled handoff around existing file search, not become another search engine. The next step should test whether owner permission, each person's existing file access, source citations, and human review solve a problem Microsoft tools cannot solve at lower cost.

Scorecard: demo checks, not real-world results

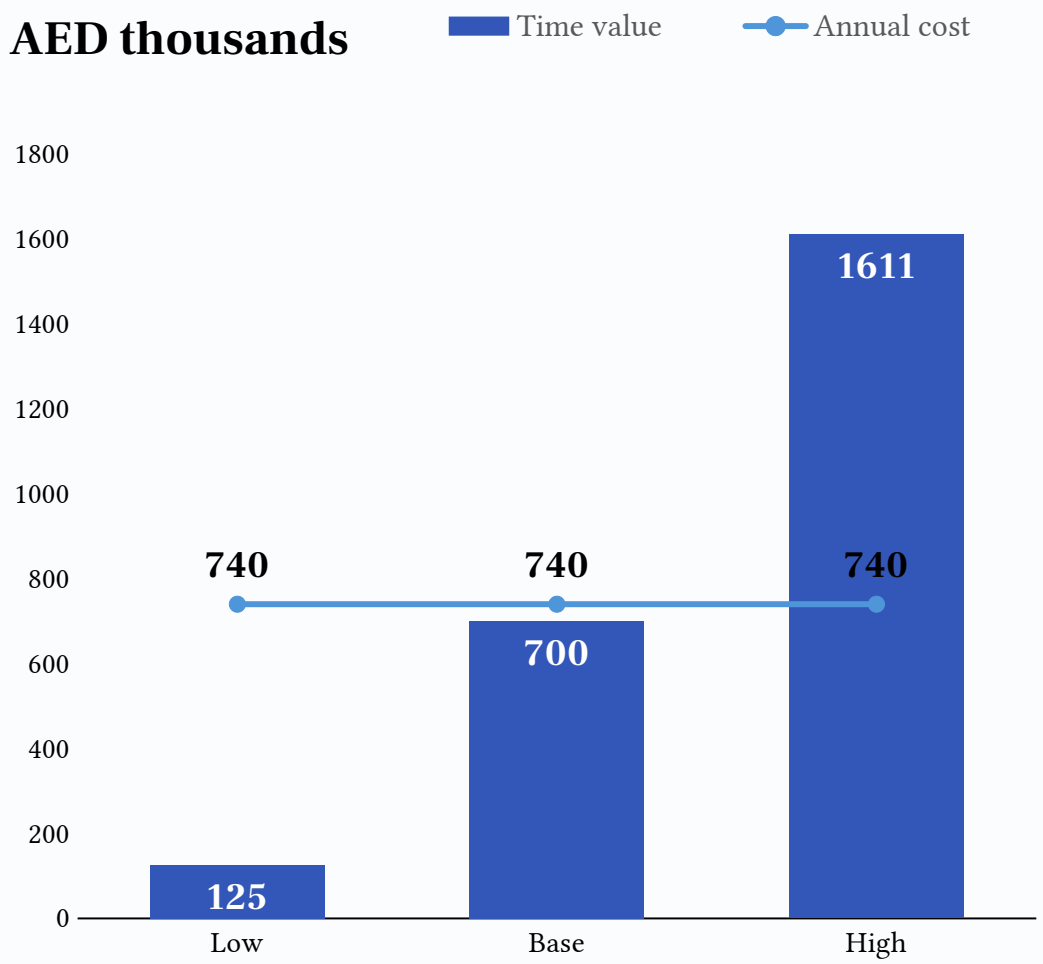

How to read this

The demo checks its rules against fictional records.

It does not measure answer accuracy, employee value, company security, or production reliability.

Measure	Current result	What it shows	Next proof
Question flow	Working locally	Policy → answer or handoff	Security review
App tests	17 passed	Expected demo rules	Integration tests
Source search	32/32 found	Word-match cases	Real questions
No-answer cases	4/4 sent to a person	No source matched	Reworded questions
Access checks	0 in tests	Scripted cases only	Company access review
Live users	Not measured	No employee pilot	Set baseline
Time saved	Not measured	Business assumption	Pilot time study
Microsoft access	Not tested	Connection code only	Work-account test
Teams app	Not built	No Teams app	Choose workflow host

Illustrative annual time value and cost

Question volume

50,000 possible questions: 500 people × 2 per week × 50 weeks.

Base-case use

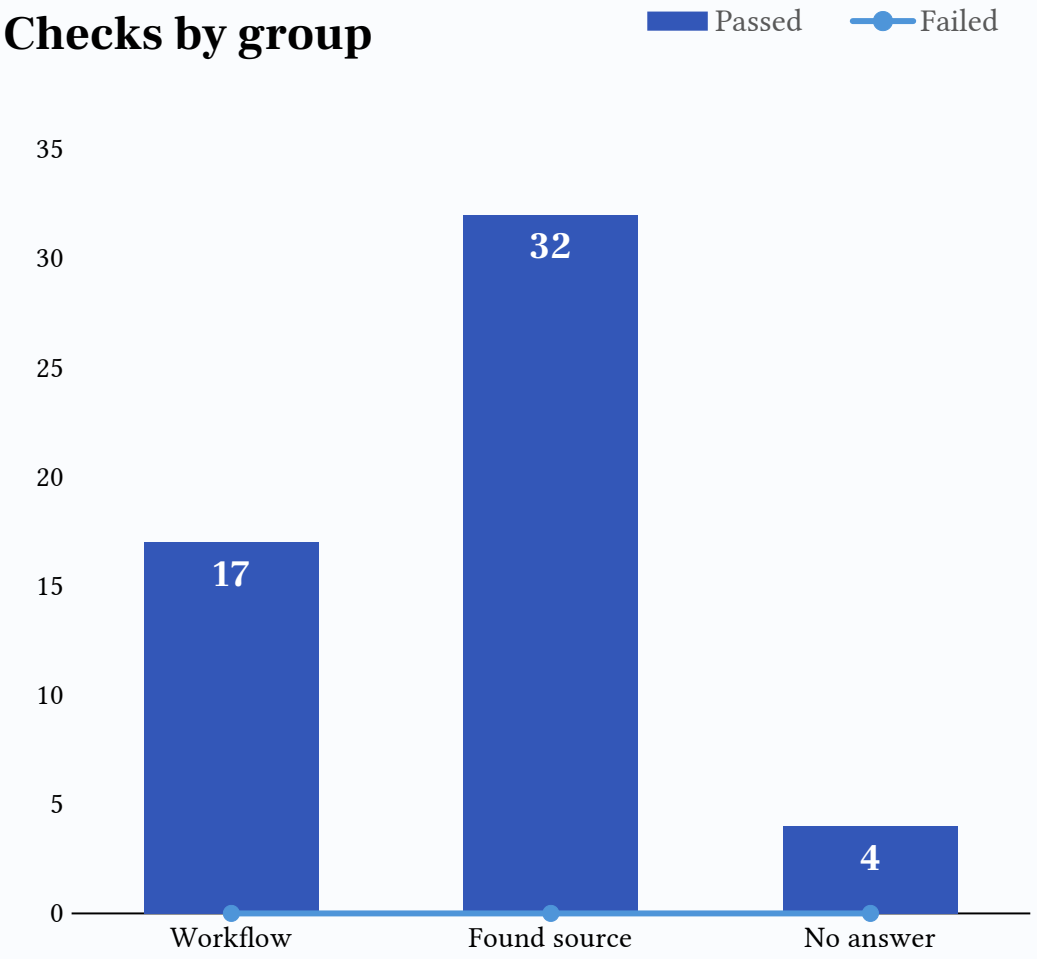

8,400 accepted answers under illustrative adoption and resolution assumptions.

Time counted

20 minutes of active search per accepted answer; waiting is excluded.

Synthetic evaluation snapshot

Checks by group

36/36

All 36 search cases matched expected results.

0

Scripted tests only; not a security proof.

17 backend tests also passed. These small synthetic checks do not assess answer quality, tenant integration, performance, adoption, or saved time.

Proposed 10-week path to a small team trial

Weeks 0–2

Safety review

Review data and file controls. Pick one willing team and record a starting point.

Weeks 2–6

Microsoft access test

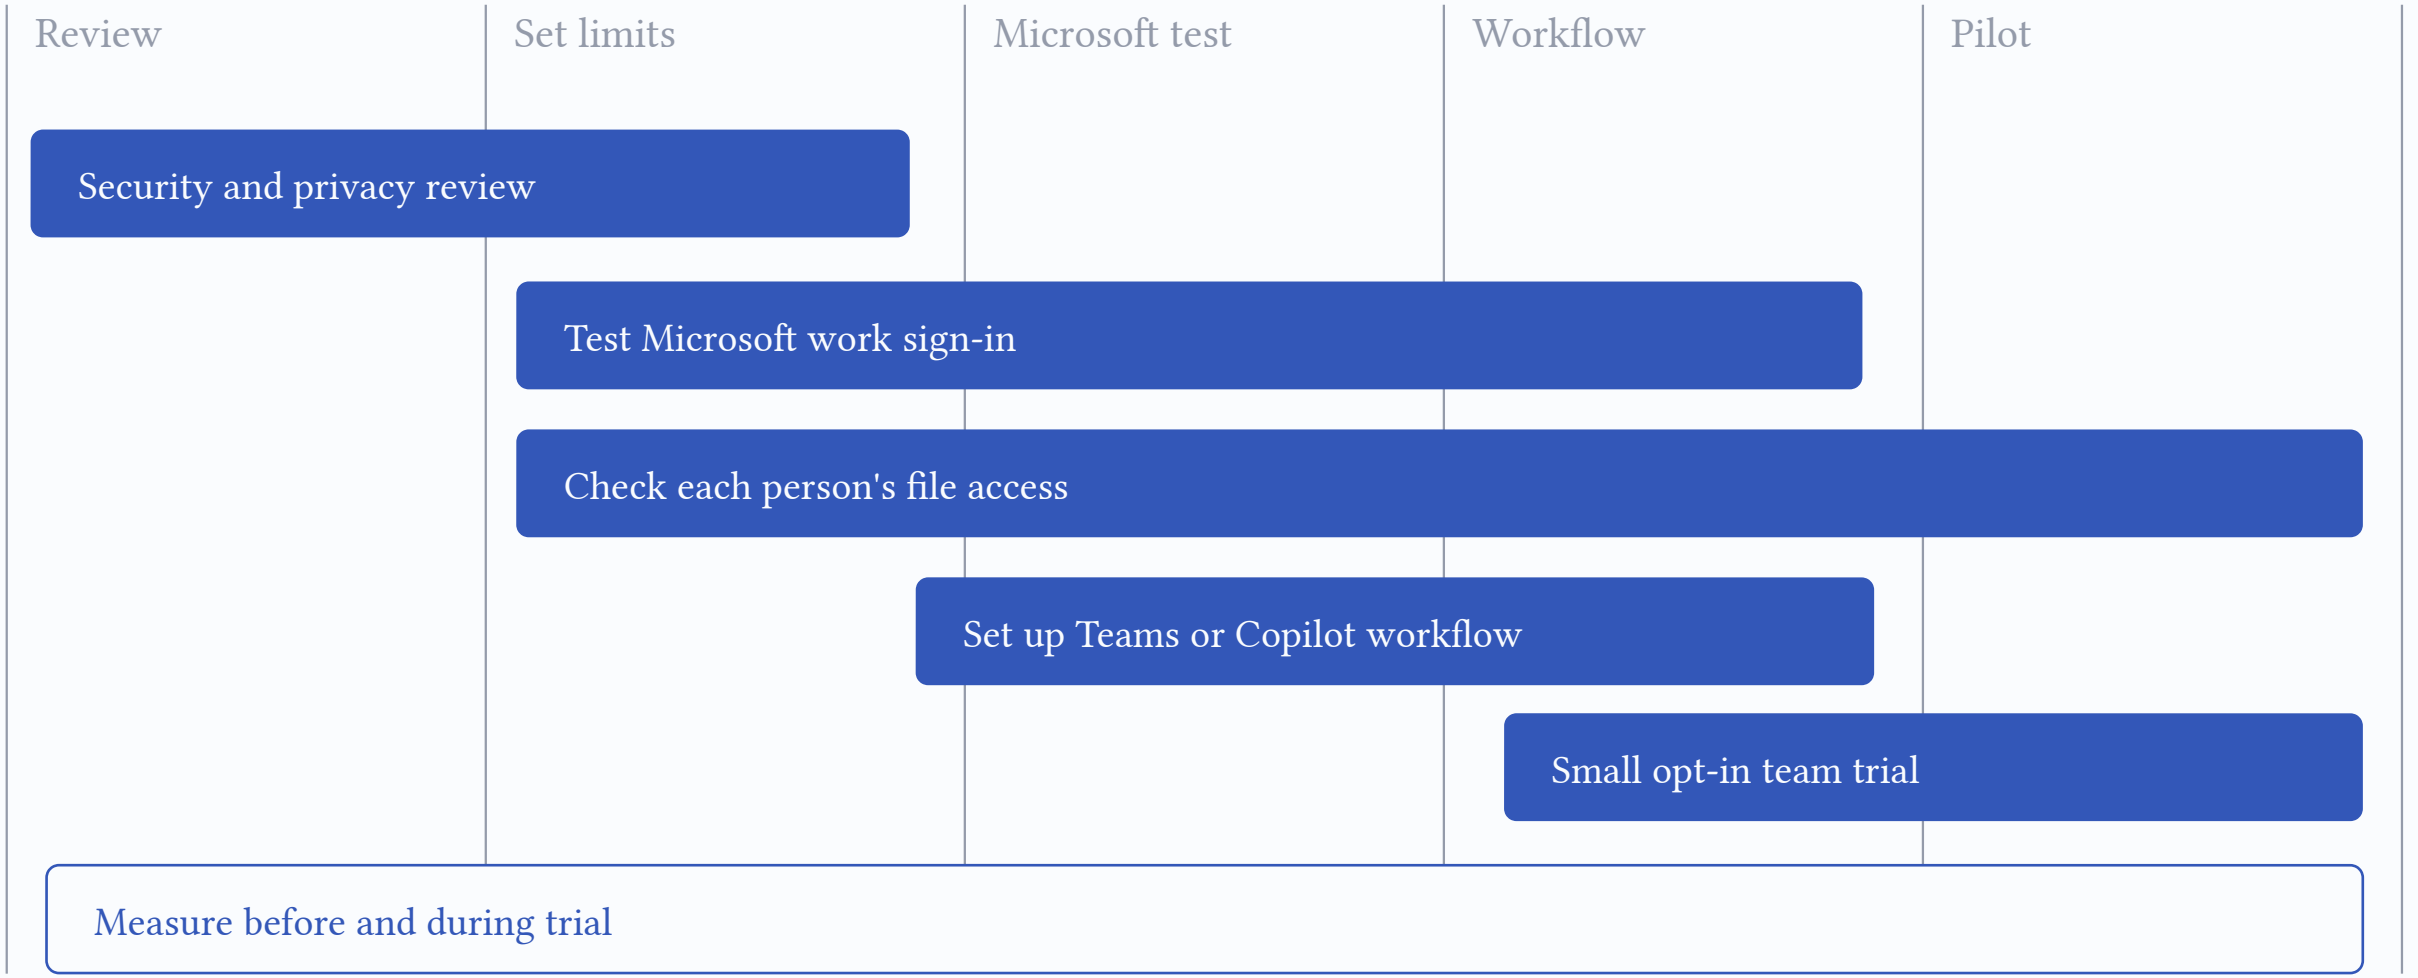

Test work-account sign-in and file access. Choose Teams or Copilot Studio.

Weeks 6–10

Small team trial

Run with one willing team. Measure time, trust, accepted answers, and access issues.

Indicative work sequence; approvals come first

Leadership decisions

Approve a security and Microsoft access review.

Choose one low-risk, willing team for a small trial.

Measure value; stop if anyone sees a file they should not.
